INVESTIGATOR	

RECOMMENDED FOR: Chief, Technical Analysis Staff
SUBJECT: Prod. Comparison

1. An extension of the basic fuel parameters does not indicate that the PWA 523 fuel is significantly better than present fuels to warrant a flight test program and/or a change in the operational fuel. The rough comparison between PWA 523 and LF-1 does yield a greater range capability of 250 nautical miles in the clean configuration and an increase of 270 miles when utilizing the sliper tanks. The above figures are for an operational mission rather than a ferry mission.
 2. The fuel presently being used in the U-23 is MILP-2592A. The specific gravity of the fuel varies from 0.776 to 0.805. If some weighted average is used for comparative evaluation, the PWA 523 fuel yields a range increase of only 50 miles clean and 90 miles with sliper tanks. If the pilot handbook fuel specific is used, these added ranges decrease to 50 and 60 miles respectively. If the upper limit of the fuel specific is used, the PWA 523 is not as good as the MILP-2592A. The difference between the MILP-2592A fuel and the alternate fuel (LF-1) is not measurable on the slide rule.
 3. Without a flight test program, no comparison can be made between the fuel start capabilities. It would require an extensive test program to determine if significant maintenance advantages would be realized by the more favorable luminosity number of PWA 523. Costs of the two fuels and manufacturing complexity comparisons are not known. Since the environment is radically different between the U-23 and the proposed A-12, there is no requirement to use the U-23 as a "test bed" in this circumstance.
 4. Based on the above, it is recommended that no flight test program be initiated to test the PWA 523 fuel for possible U-23 use.
